# **Knowledge Organiser: Programming**

## **Summarv**

**Programming** is writing computer code to create a program, in order to solve a problem. Programs consist of a series of instructions to tell a computer exactly what to do and how to do it.

An **algorithm** is a set of instructions that describes how to get something done. It is crucial that the steps in an algorithm are sequenced and performed in the right order - otherwise the algorithm will not work correctly. Algorithms can be designed using **pseudocode** and **flow charts**. They are written using **statements** and **expressions**. There are three basic building blocks (constructs) to use when designing algorithms: sequencing, selection and iteration. We create programs to implement algorithms. Algorithms consist of steps, where programs consist of statements.

In programming, iteration is often referred to as 'looping', because when a program iterates it 'loops' to an earlier step. It is implemented using FOR and WHILE statements. Selection is implemented in programming using **IF** statements.

### Variable

# Computer programs use variables to store information.

Variables could be used to store the score in a game, the number of cars in a car park or the cost of items on a till. They work in a similar way to algebra, where a letter in your code can stand for a number.

## Selection

#### Selection is a decision or question.

because it has reached a step where one or more options we will repeat certain steps until told otherwise. This are available. Depending on the answer given, the program makes designing algorithms quicker and simpler because will follow a certain step and ignore the others.

## Sequencing

Sequencing is the specific order in which instructions are performed in an algorithm.

Algorithms consist of instructions that are carried out (performed) one after another.

#### Iteration

#### Iteration is the process of repeating steps.

At some point, a program may need to ask a question Iteration allows us to simplify our algorithm by stating that they don't have to include lots of unnecessary steps.

# **Key Vocabulary**

| Algorithm               | A sequence of logical instructions for carrying out a task. In computing, algorithms are needed to design computer programs.                     |  |
|-------------------------|--|--|
| Flowchart               | A diagram that shows a process, made up of boxes representing steps, decision, inputs and outputs.   |  |
| Instruction             | A single action that can be performed by a computer processor.   |  |
| Programming             | The process of writing computer software.  |  |
| Programming<br>language | A language used by a programmer to write a piece of software. There are many programming languages.  |  |
| Pseudocode              | A method of writing up a set of instructions for a computer program using plain English. This is a good way of planning a program before coding. |  |
| Variable                | In a computer program, this is a memory location where values are stored.  |  |

# Algorithms

Algorithms can be represented as pseudocode or a flowchart, and programming is the translation of these into a computer program.

# **Knowledge Organiser: Programming**

## Summary

Sometimes we need computers to remember the information we give it and that it calculates during programs. A **variable** can be thought of as a box that the computer can use to store a value. The value held in that box can change or 'vary'.

A program can use as many variables as it needs it to. **Variables are a key element of programming.** They are used for calculations, for storing values for later use, in decisions and in iteration. It is important to use meaningful names for variables.

Programs require data to be **input**. This data is used (**process**ed) by the program, and data (or information) is **output** as a result. Once data has been processed, programs often need to output the data they have generated. In Python, the **'print' statement** is used to output data.

| Python Language & Syntax   |   |  |   |   |  |
|--|---|--|---|---|--|
| Control Flow   |   |  | Comparisons   |   |  |
| if conditional:<br><body><br/>elif conditional:<br/><body><br/>else:<br/><body><br/>for value in list:<br/><body><br/>continue<br/>break</body></body></body></body>                                     | <pre>if i == 7:<br/>print "seven"<br/>e.g. elif i == 8:<br/>print "eight"<br/>else:<br/>print str(i)<br/>for i in [1, 2, 3, 4]:<br/>e.g. if i == 2: continue<br/>if i == 3: break<br/>print i</pre> | <pre>value1 == value2 value1 != value2 value1 &lt; value2 value1 &lt;= value2 value1 &gt;&gt; value2 value1 &gt;&gt; value2 value is [not] None value in list isinstance(class ins</pre> | "str"<br>1 < 2<br>2 <=<br>2 > 3<br>3 >=<br>1 in [<br>tance, ClassNa | == "str" → True<br>== "str" → False<br>2 → True<br>2 → True<br>3 → False<br>3 → True<br>$(2,3,4] \rightarrow False$<br>ame) |  |

| integer = 1  |   | i = a + b  | i=a   | - b   |  |
| <pre>string = "string" unicode_string = u"unicode string" mutli_line_string = """ multi-line     string     """</pre>  |   | i = a % b  | e.g. 11 %   | ilt-in Types  |  |
| <pre>tuple = (element1, element2, element3,) list = [ element1, element2, element3, ] dictionary = { key1 : value1, key2 : value2, } dictionary[key] = value class_instance = ClassName(init_args)</pre> |   | True<br>str<br>float<br>Other than True, Fals<br>functions to e  | False<br>unicode<br>list<br>se and None, t<br>xplicitly cast a      | None<br>int<br>dict<br>hese can also be used as<br>value to that type   |  |

## **Key Vocabulary**

| Assignment             | Setting the value of a variable in a computer program.  |  |
|------------------------|---|--|
| Constant               | A value in computer programming that does not change.   |  |
| Data Type              | In computer programming, data is divided up<br>and organised according to type, e.g.<br>numbers, characters and Boolean.  |  |
| Debug                  | The process of finding and correcting programming errors.   |  |
| Execute                | To run a computer program.  |  |
| High-level<br>language | A computer programming language used to<br>write programs. They need to be translated<br>into machine code through a compiler,<br>interpreter or assembler.           |  |
| Machine<br>code        | Also called object-code, this is low-level code<br>that represents how computer hardware and<br>CPUs understand instructions. It is<br>represented by binary numbers. |  |
| Runtime                | The period when a computer program is executing or running.   |  |
| Syntax                 | Rules governing how to write statements in a programming language.  |  |

# **Data types**

Different types of data are represented in different ways inside a computer and need varying amounts of memory to store them.

| Data type                      | Example           | Size        |
|--------------------------------|-------------------|-------------|
| Integer (whole number)         | 4, 27, 65535      | 1 - 8 bytes |
| Floating point (decimal number | 4.2, 27.4, 5.63   | 4 - 8 bytes |
| Character                      | A, a, 3, \$, £, # | 1 byte      |
| String                         | Abc, hello world  | Limited     |
| Boolean                        | true or false     | 1 bit       |
