

From power stations	<b>Electrical energy is transferred at high voltages</b>	Improves the efficiency by reducing heat loss in transmission lines.
To homes, factories and buildings	<b>Electrical energy is transferred at lower voltages</b>	Makes it safer for appliances and users

Step-up transformers	Step-down transformers
<b>Increase voltage, decrease current</b>	<b>Decrease voltage, increase current</b>
Increases efficiency, reduces heat loss.	Makes safer for houses.

**Electromagnetic induction**

**The induction of potential difference across an electrical conductor which is affected by a change in an external magnetic field.**

p.d. can be induced in two ways:

- Moving the conductor in a magnetic field
- Changing or moving the magnetic field

**Factors affecting size of induction**

Depends on:

- Number of turns in a coil
- The strength of magnetic field
- How fast the wire moves or the magnetic field changes.

Reversing the magnetic field, reverses the direction of the induced p.d.

A changing magnetic field can induce a p.d. in a wire. Current then flows.

A coil is used so there is more wire in the changing magnetic field.

<b>Generators</b>	<b>Coil of wire rotating inside a magnetic field. The end of the coil is connected to slip rings.</b>	Produces altering current.
<b>Dynamo</b>	<b>Coil of wire rotating inside a magnetic field. A commutator switches over the connection every half turn.</b>	Produces direct current.

**Loud speakers**

**Converts variations in electrical current into sound waves.**

Varying current flows through a coil that is in a magnetic field. A force on the wire moves backwards and forwards as current varies. Coil connected to a diaphragm. Diaphragm movements produce sound waves.

**Microphones**

**Converts pressure variations in sound waves into variations in current in electrical circuits.**

Potential difference across primary coil ÷ Potential difference across secondary coil = Number of turns on primary coil ÷ Number of turns on secondary coil

$$V_p \div V_s = N_p \div N_s$$

Potential difference across primary coil X current in primary coil = Potential difference across secondary coil X current in secondary coil

$$V_p \times I_p = V_s \times I_s$$

**PHYSICS HIGHER ONLY**

Transmitting power at high voltage is more efficient

Use these questions to prove this.

$$\text{Power} = \text{Energy transferred} \div \text{time taken}$$

$$\text{Electrical Power} = \text{Current} \times \text{Potential difference}$$

$$\text{Power} = \text{Current squared} \times \text{Resistance}$$

	<i>Electrical energy is transferred at high voltages</i>	Improves the efficiency by reducing heat loss in transmission lines.
	<i>Electrical energy is transferred at lower voltages</i>	Makes it safer for appliances and users

	<i>Increase voltage, decrease current</i>	<i>Decrease voltage, increase current</i>
	Increases efficiency, reduces heat loss.	Makes safer for houses.

*The induction of potential difference across an electrical conductor which is affected by a change in an external magnetic field.*

p.d. can be induced in two ways:

- Moving the conductor in a magnetic field
- Changing or moving the magnetic field

*Distributes electricity generated in power stations around UK*

*Change the size of alternating voltage*

Made up of two coils of insulated wire wound on an iron core.

Alternating current in the primary coil creates a magnetic field, which is constantly changing.

The magnetic field is carried to the secondary coil by the iron core.

The magnetic field induces a changing potential difference in the secondary coil.

Depends on:

- Number of turns in a coil
- The strength of magnetic field
- How fast the wire moves or the magnetic field changes.

**HIGHER ONLY**

**Electromagnetic induction**

**The National Grid**

**HIGHER ONLY**

	<i>More turns on secondary coil</i>	Potential difference increases
	<i>More turns on primary coil</i>	Potential difference decreases

Reversing the magnetic field, reverses the direction of the induced p.d.

A changing magnetic field can induce a p.d. in a wire. Current then flows.

A coil is used so there is more wire in the changing magnetic field.
